APPLICATION ELEMENTS
See MPEP chapter 600 concerning utility patent application contents.

ADDRESS TO: **Assistant Commissioner for Patents, Box Patent Application, Washington, DC 20231**

1. [X] * Fee Transmittal Form (e.g., PTO/SB/17) (Submit an original and a duplicate for fee processing)
2. [X] Specification [Total Pages 33] (preferred arrangement set forth below)
   - Descriptive title of the Invention
   - Cross References to Related Applications
   - Statement Regarding Fed sponsored R & D
   - Reference to Microfiche Appendix
   - Background of the Invention
   - Brief Summary of the Invention
   - Brief Description of the Drawings (if filed)
   - Detailed Description
   - Claim(s)
   - Abstract of the Disclosure
3. [X] Drawing(s) (35 U.S.C. 113) [Total Sheets 6]
4. Oath or Declaration [Total Pages 3]
   a. [ ] Newly executed (original or copy)
   b. [X] Copy from a prior application (37 C.F.R. § 1.63(d)) (for continuation/divisional with Box 16 completed)
      i. [ ] DELETION OF INVENTOR(S) Signed statement attached deleting inventor(s) named in the prior application, see 37 C.F.R. §§ 1.63(d)(2) and 1.33(b).

* NOTE FOR ITEMS 1 & 13: IN ORDER TO BE ENTITLED TO PAY SMALL ENTITY FEES, A SMALL ENTITY STATEMENT IS REQUIRED (37 C.F.R. § 1.27), EXCEPT IF ONE FILED IN A PRIOR APPLICATION IS RELIED UPON (37 C.F.R. § 1.28).

5. [ ] Microfiche Computer Program (Appendix)
6. Nucleotide and/or Amino Acid Sequence Submission (if applicable, all necessary)
   a. [ ] Computer Readable Copy
   b. [ ] Paper Copy (identical to computer copy)
   c. [ ] Statement verifying identity of above copies

ACCOMPANYING APPLICATION PARTS

7. [ ] Assignment Papers (cover sheet & document(s))
8. [ ] 37 C.F.R.§3.73(b) Statement (when there is an assignee) [ ] Power of Attorney
9. [ ] English Translation Document (if applicable)
10. [ ] Information Disclosure Statement (IDS)/PTO-1449 [ ] Copies of IDS Citations
11. [X] Preliminary Amendment
12. [X] Return Receipt Postcard (MPEP 503) (Should be specifically itemized)
13. [ ] * Small Entity Statement(s) (PTO/SB/09-12) [ ] Statement filed in prior application, Status still proper and desired
14. [ ] Certified Copy of Priority Document(s) (if foreign priority is claimed)
15. [ ] Other: ....

16. If a **CONTINUING APPLICATION,** check appropriate box, and supply the requisite information below and in a preliminary amendment

[X] Continuation [ ] Divisional [ ] Continuation-in-part (CIP) of prior application No: 09 / 088,820

Prior application information: Examiner Jeffrey Fredman Group / Art Unit: 1655

For CONTINUATION or DIVISIONAL APPS only: The entire disclosure of the prior application, from which an oath or declaration is supplied under Box 4b, is considered a part of the disclosure of the accompanying continuation or divisional application and is hereby incorporated by reference. The incorporation can only be relied upon when a portion has been inadvertently omitted from the submitted application parts.

PRELIMINARY AMENDMENT

Sir:

Prior to examination on the merits, please amend the application identified above as follows.

IN THE SPECIFICATION

At page 1, line 5, immediately after the phrase "This application is" please insert: - - a continuation of application serial number 09/088,820, which is a continued prosecution application of application serial number 09/088,820, filed June 2, 1998, which is- -.

At page 1, line 10, immediately after the phrase "This immediate parent application" please insert: - - (application serial number 08/173,173)- -.

REMARKS

A final office action for the parent application Serial No. 09/088,820 was mailed on January 24 ,2000. Accordingly, Applicants have enclosed herewith a three-month extension of time along with a check for $870.00. Thus the present continuation application is filed herewith

Certificate of Express Mail Under 37 CFR 1.10
I hereby declare that this correspondence is being deposited with the United States Postal Service via Express Mail Label No. EL301953995US in an envelope addressed to: Commissioner of Patents and Trademarks,Washington, DC 20231

AUTOMATIC GENOTYPE DETERMINATION

Cross Reference to Related Applications

This application is a continuation of application serial no. 08/362,266, filed December 22, 1994, which is a continuation in part of application serial no. 08/173,173, filed December 23, 1993, which is for an invention entitled "Automatic Genotype Determination," by Stephen E. Lincoln and Michael P. Knapp. This immediate parent application is a continuation in part of application serial no. 07/775,786, filed October 11, 1991, for an invention entitled "Nucleic Acid Typing by Polymerase Extension of Oligonucleotides using Terminator Mixtures," by P. Goelet, M. Knapp, and S. Anderson, which in turn is a continuation in part of application serial no. 07/664,837, filed March 5, 1991. Immediate parent application serial no. 08/173,173 is also a continuation in part of application serial no. 08/162,397, filed December 6, 1993, for an invention entitled "Method for Immobilization of Nucleic Acid Molecules" by T. Nikiforov and M. Knapp, and of application serial no. 08/155,746, filed November 23, 1993, for an invention entitled "Method for Generating Single-Stranded DNA Molecules" by T. Nikiforov and M. Knapp, and of application serial no. 08/145,145, filed November 3, 1993, for an invention entitled "Single Nucleotide Polymorphisms and their use in Genetic Analysis" by M. Knapp and P. Goelet. All of these related applications are hereby incorporated herein by reference.

Technical Field

The present invention relates to the methods and devices for determining the genotype at a locus within genetic material.

Summary of the Invention

The present invention provides in one embodiment a method of determining the genotype at a locus within genetic material obtained from a biological sample. In accordance with this method, the material is reacted at the locus to produce a first reaction value indicative of the presence of a given allele at the locus. There is formed a data set including the first reaction value. There is also established a set of one or more probability distributions; these distributions associate hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus. The first reaction value is applied to each probability distribution to determine a measure of the conditional probability of each genotype of interest at the locus. The genotype is then determined based on these measures.

In accordance with a further embodiment of this method, the material at the locus is subject to a second reaction to produce a second reaction value independently indicative of the presence of a second allele at the locus. A second data set is formed and the second reaction value is included in the second data set. Each probability distribution associates a hypothetical pair of first and second reaction

values with a single probability of each genotype of interest. The first data set includes other reaction values obtained under conditions comparable to those under which the first reaction value was produced, and the second data set includes other reaction values obtained under conditions comparable to those under which the second reaction value was produced. Where, for example, there are two alleles of interest, the first reaction may be an assay for one allele and the second reaction may be a distinct assay for the other allele. The first and second data sets may include reaction values for the first and second reactions respectively, run under comparable conditions on other samples with respect to the same locus. Alternatively, or in addition, the data sets may include reaction values for reactions run under comparable conditions with respect to different loci within the same sample.

In accordance with a further embodiment, the probability distributions may be determined iteratively. In this embodiment, each probability distribution is initially estimated. Each initial probability distribution is used to determine initial genotype probabilities using the reaction values in the data sets. The resulting data are then used to modify the initial probability distribution, so that the modified distribution more accurately reflects the reaction values in the data set. This procedure may be iterated a desired number of times to improve the probability distribution. In practice, we have generally found that a single iteration is sufficient.

The foregoing methods have been employed with success for automatic genotype determination based on assays using genetic bit analysis (GBA). In such a case, each allele may typically be a single specific nucleotide. In accordance with GBA, a reaction is designed to produce a value that is indicative of the presence of a specific allele at the locus within the genetic material. In GBA, the approach is typically to hybridize a specific oligonucleotide to the genetic material at the locus immediately adjacent to the nucleotide being interrogated. Next, DNA polymerase is applied in the presence of differentially labelled dideoxynucleoside triphosphates. The read-out steps detect the presence of one or more of the labels which have become covalently attached to the 3' end of the oligonucleotide. Details are provided in Theo R. Nikiforov et al. "Genetic Bit Analysis, a solid phase method for typing single nucleotide polymorphisms," 22 Nucleic Acids Research, No. 20, 4167-4175 (1994), which is hereby incorporated herein by reference. However, the present invention is also applicable to other reaction systems for allele determination, such as allele-specific hybridization (ASH), sequencing by hybridization (CBH), oligonucleotide ligase assay (OLA), and allele-specific amplification, using either the ligase chain reaction (LCR) or the polymerase chain reactions (PCR). The alleles assayed may be defined, for example, by a single nucleotide, a pair of nucleotides, a restriction site, or (at least in part) by its length in nucleotides.

In another embodiment of the invention, there is

provided a method of determining the genotype of a subject by reacting genetic material taken from the subject at selected loci. In this embodiment, each locus may be an identified single nucleotide or group of nucleotides, and there is produced with respect to each of the selected loci a reaction value indicative of the presence of a given allele at each of the selected loci. These reaction values are used to determine the genotype of the subject or alternatively a DNA sequence associated with a specific region of genetic material of the subject. (Indeed a set of genotypes for selected proximal loci may be used to specify a sequence of the genetic material.). In further embodiments, the loci are selected to provide one or more types of information concerning the subject, including inheritance of a trait, parentage, identity, and matching tissue with that of a donor. Alternatively, the loci may be spaced throughout the entire genome of subject to assist in characterizing the genome of the species of the subject.

In a further embodiment of the invention, there is provided a device for determining the genotype at a locus within genetic material obtained from a subject. The device of this embodiment has a reaction value generation arrangement for producing a first physical state, quantifiable as a first reaction value, indicative of the presence of a given allele at the locus, the value associated with reaction of the material at the locus. The device also has a storage arrangement for storing a data set including the first reaction value and other reaction values

obtained under comparable conditions. A distribution establishment arrangement establishes a set of probability distributions, including at least one distribution, associating hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus. A genotype calculation arrangement applies the first reaction value to each pertinent probability distribution to determine the conditional probability of each genotype of interest at the locus. A genotype determination arrangement determines the genotype based on data from the genotype calculation arrangement.

In a further embodiment, the device may determine the genotype at selected loci. In this embodiment, the reaction generation arrangement can produce a reaction value indicative of the presence of a given allele at each of the selected loci and the data set includes reaction values obtained with respect to each of the selected loci. The genotype calculation arrangement applies reaction values obtained with respect to each of the selected loci to each pertinent probability distribution.

In another further embodiment, the device may determine the genotype at a locus within genetic material from each of a plurality of samples. In this embodiment, the reaction generation arrangement can produce a reaction value indicative of the presence of a given allele at the locus of material obtained from each sample and the data set includes reaction values obtained with respect to each sample. The genotype calculation arrangement applies reaction values

obtained with respect to each sample to each pertinent probability distribution.

In each of these embodiments the reaction value generation arrangement may also include an arrangement for producing a second reaction value, independently indicative of the presence of a second allele at the locus. The storage arrangement then includes a provision for storing the second reaction value and other reaction values obtained under comparable conditions. The genotype calculation arrangement applies the first and second reaction values to each pertinent probability distribution to determine the probability of each genotype of interest at the locus. Each probability distribution may be of the type associating a hypothetical pair of first and second reaction values with a single probability of each genotype of interest. The locus may be a single nucleotide, and the reaction value generation arrangement may include an optical transducer to read reaction results and may determine, on a substantially concurrent basis, the reaction values with respect to each sample.

The distribution establishment arrangement may be configured to assign an initial probability distribution to the data set that would associate hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus. The distribution establishment arrangement then invokes the genotype calculation means to use each initial probability distribution to determine initial conditional probabilities for a genotype of interest

at the locus. Thereafter the distribution establishment arrangement modifies each initial probability distribution, so that each modified distribution more accurately reflects the reaction values stored in the storage means.

The term "reaction value" as used in this description and the following claims may refer either to a single numerical value or to a collection of numbers associated with a physical state produced by the reaction. In the GBA method described in the Nikiforov article referred to above, e.g., optical signals are produced that may be read as a single numerical value. Alternatively, e.g., an optical signal may be simplified over time, and the reaction value may be the collection of samples of such a signal. It is also possible to form a scanned image, of one or a series of optical signals generated by GBA or other reaction methods, and to digitize this image, so that a collection of pixel values in all or a portion of the image constitutes a reaction value.

Brief Description of the Drawings

The foregoing aspects of the invention will be more readily understood by reference to the following detailed description, taken with respect to the following drawings, in which:

Fig. 1 is a diagram of a device in accordance with a preferred embodiment of the invention;

Fig. 2 is a diagram of the logical flow in accordance

with the embodiment of Fig. 1;

Fig. 3 is a graph of numeric reaction values (data) generated by the embodiment of Fig. 1 as well as the genotype determinations made by the embodiment from these data; and

Figs. 4-7 show probability distributions derived by the embodiment of Fig. 1 for three genotypes of interest (AA, AT, and TT) and a failure mode at a locus.

Fig. 8 is an example of the output of the device in Fig. 1.

Detailed Description of Specific Embodiments

The invention provides in preferred embodiments a method and device for genotype determination using genetic marker systems that produce allele-specific quantitative signals. An embodiment uses computer processing, employing computer software we developed and call "GetGenos", of data produced by a device we also developed to produce GBA data. The device achieves, among other things, the following:

- Fully automatic genotype determination from quantitative data. Off-line analysis of data pools is intended, although the software is fast enough to use interactively.
- Ability to examine many allele tests per DNA sample simultaneously. One genotype and confidence measure are produced from these data.
- A true probabilistic confidence measure (a LOD

score), properly calibrated, is produced for each genotype.

• Use of robust statistical methods: Noise reduction via selective data pooling and simultaneous search over points in a data pool, preventing bias.

• Maximal avoidance of arbitrary parameters, and thus insensitivity to great variation in input data. The small number of parameters that are required by the underlying statistical model are fit to the observed data, essentially using the data set as its own internal control.

• Flexibility for handling multiple data types. Essentially, only probability distribution calculations, described below, need to be calibrated to new data types. We expect that the invention may be applied to GBA, OLA, ASH, and RAPD-type markers.

Our current embodiment of the software is implemented in portable ANSI C, for easy integration into a custom laboratory information system. This code has been successfully run on:

• Macintosh
• Sun
• MS-DOS
• MS-Windows

In our current embodiment of the software, a number of consistency checks are performed for GBA data verification, using both the raw GBA values and the control wells. Overall statistics for trend analysis and QC are computed. Brief "Genotype Reports" are generated, summarizing results for each data set, including failures. All data are output

in a convenient form for import into interactive statistical packages, such as DataDesk™. The current implementation is presently restricted to 2-allele tests in diploids - the situation with present GBA applications.

Referring to Fig. 1, there is shown a preferred embodiment of a device in accordance with the present invention. The device includes an optical detector 11 to produce reaction values resulting from one or more reactions. These reactions assay for one or more alleles in samples of genetic material. We have implemented the detector 11 using bichromatic microplate reader model 348 and microplate stacker model 83 from ICN Biomedical, Inc., P.O. Box 5023, Costa Mesa, California 92626. The microplates are in a 96 well format, and the reader accommodates 20 microplates in a single processing batch. Accordingly the device of this embodence permits large batch processing. The reactions in our implementation use GBA, as described above. The detector 11 is controlled by computer 12 to cause selected readout of reaction values from each well. The computer 12 is programmed to allow for multiple readout of the reaction value from a given well over a period of time. The values are stored temporarily in memory and then saved in database 14. Computer 13 accesses the database 14 over line 15 and processes the data in accordance with the procedure described below. Of course, computers 12 and 13 and database 14 may be implemented by an integral controller and data storage arrangement. Such an arrangement could in fact be located in the housing of the optical detector 11.

In Fig. 2 is shown the procedure followed by computer 13. The steps of this procedure are as follows:

Input Data: A set of data is loaded under step 21. In most applications, each experiment in the set should be testing (i) the same genetic marker, and (ii) the same set of alleles of that marker, using comparable biochemistry (e.g. the same reagent batches, etc.). Large data sets help smooth out noise, although the appropriate size of a data set depends on the allele frequencies (and thus the number of expected individuals of each genotypic class). Each data point in the input data may be thought of as an N-tuple of numeric values, where N is the number of signals collected from each DNA sample for this locus. (N will usually be the number of alleles tested at this marker, denoted A, except when repeated testing is used, in which case N may be greater than A).

Preprocess Data: Next the data are subject to preprocessing (step 22). An internal M-dimensional Euclidean representation of the input signals is produced, where each input datum (an N-tuple) is a point in M-space. Usually, M will be the same as N and the coordinates of the point will be the values of the input tuple, and thus the preprocessing will be trivial (although see the first paragraph of variations discussed). The Euclidean space may be non-linear, depending on the best available models of signal generation. (Completely mathematically equivalently, any non-linearity may be embodied in the initial probability distributions, described below.)

Fig. 3 illustrates preprocessed reaction values from step 22 for GBA locus 177-2 on 80 DNA samples. The X-axis indicates preprocessed reaction values for allele 1 (A) and the Y-axis indicates preprocessed reaction values for allele 2 (T). For clarity, the results of genotype determination are also indicated for each point: Triangles are TT genotype, diamonds are AA, circles are AT, and squares are failures (no signal).

Probability Distributions: Returning to Fig. 2, under step 22, initial probability distributions are established for the G possible genotypes. For example, in a random diploid population containing A tested alleles:

$$G = (A) + (A - 1) + \ldots + 1 = \frac{A(A + 1)}{2} \qquad (1)$$

The initial conditional probability for any hypothetical input datum (a point in M-space, denoted X_i) and genotype (denoted g) is defined as the prior probability of seeing the signal X_i assuming that g is the correct genotype of that datum. That is:

$$\Pr(\text{signal } X_i \bullet \text{Genotype} = g),$$
$$\text{where } X_i = (x_i^1 \ \ldots \ x_i^M) \text{ and } g \bullet \{1 \ldots G\} \qquad (2)$$

Figures 4 through 7 illustrate the initial probability distributions established for the data in figure 3. Probability distributions are indicated for the four

genotypic classes of interest, AA, AT, TT and No Signal, in Figs 4, 5, 6, and 7 respectively. The shading at each XY position indicates probability, with darker shades indicating increased probability for hypothetical data points with those X and Y reaction valves.

Exactly where these distributions come from is highly specific to the nature of the input data. The probability distributions can either be pre-computed at this step and stored as quantized data, or can be calculated on the fly as needed in step 23, below. The probability distributions may be fixed, or may be fit to the observed data or may be fit to assumed genotypes as determined by previous iterations of this algorithm. (See Additional Features below.)

Under step 23, we compute the conditional probability of each genotype. For each datum X_i, the above probabilities are collected into an overall conditional posterior probability of each genotype for that datum:

$$\Pr(\text{Genotype} = g \mid \text{Signal } X_i) = \frac{\Pr(\text{Signal } X_i \mid \text{Genotype} = g) \cdot \Pr(\text{Genotype} = g)}{\Pr(\text{Signal } X_i)} \quad (3)$$

where

$\Pr(\text{Genotype} = g)$ is the prior probability of any datum having genotype g;

$\Pr(\text{Signal } X_i)$ is the prior probability of the signal (a constant which may be ignored); and

$\Pr(\text{Signal } X_i \cdot \text{Genotype} = g)$ is the initial probability defined above.

Under step 24, we determine the select the genotype and compute the confidence score. For each datum, using the above posterior probabilities, we determine the most likely genotype assignment g' (the genotype with the highest posterior probability) and its confidence score. The confidence score C is simply the loa of the odds ratio:

$$C = \log_{10} \frac{\Pr(\text{Genotype} = g' \mid \text{Signal } X_i)}{\sum_{\text{Genotypes } g} \Pr(\text{Genotype} = g \cdot \text{Signal } X_i)} \quad (4)$$

It should be noted that this procedure is significant, among other reasons, because it permits determining a robust probabalistic confidence score associated with each geno type determination.

Under step 25, there may be employed adaptive fitting. A classic iterative adaptive fitting algorithm, such as Estimation-Maximization (E-M), may be used to increase the ability to deal with highly different input data sets and reduce noise sensitivity. In this case, the genotypes computed in step 24 are used to refit the distributions (from step 22). In step 25, a convergence test is performed, which may cause the program to loop back to step 23, but now using the new distributions.

As one example, an E-M search procedure may be used to maximize the total likelihood, that is, to find the maximally likely set of genotype assignments given the input data set. (The net likelihood may be calculated from the Baysean probabilities, defined above.) For appropriate

likelihood calculations and probability distributions, the EM principle will guarantee that this algorithm always produces true-maximum-likelihood values, regardless of initial guess, and that it always converges.

Output Data: Under step 26, we output the results (genotypes and confidence scores) to the user or to a computer database. An example of such output is shown in Fig. 8.

Additional Features

Additional features may be incorporated into the above procedure. They may be integrated into the procedure either together or separately, and have all been implemented in a preferred embodiment.

Preprocessing: During steps 21 or 22, the data (either input tuples or spatial data points) may be preprocessed in order to reduce noise, using any one of many classical statistical or signal-processing techniques. Control data points may be used in this step. In fact, various types of signal filtering or normalizing may be applied at almost any step in the algorithm.

Fitting Probability Distributions: The probability distributions calculated in steps 22 and 23 may be fit to the input data - that is, each distribution may be a function of values which are in part calculated from the input data. For example, we may define the conditional probability of a signal point for some genotype to be a function of the distance between that point and the observed mean for that signal.

Using an Initial Genotype Guess: In step 22, either a simple or heuristic algorithm may be used to produce an initial genotype guess for each input data point. If a fairly accurate guess can be produced, then the probability distributions for each genotype may be fit to the subset of the data assumed to be of that genotypic class. Another use of a genotype guess is in initial input validity checks and/or preprocessing (e.g. Step 22), before the remainder of the algorithm is applied. To be useful, a guess need not produce complete genotypic information, however.

Using a Null Genotypic Class: In steps 22 and all further steps, one (or more) additional probability distributions may be added to fit the data to the signals one would expect to see if an experiment (e.g. that datum) failed. E.g.,

$$\Pr(\text{signal } X_i \bullet \text{Genotype} \bullet \{1 \ldots G\})$$

The current implementation above is presently restricted to M=2 and N=2*R, where R is the number of repeated tests of both alleles. We refer to the two alleles as X and Y. The program understands the notion of "plates" of data, a number of which make up a data set.

The Initial Guess Variation is employed to initially fit distributions using the heuristic described below. The Initial Guess is produced during the Preprocessing Step which normalizes and background subtracts the input data, and remove apparent outlier points as well. These steps are

performed separately for each allele's signal (i.e., 1 dimensional analysis). In fact, this preprocessing is applied separately to each of the R repeated tests, and the test with the small total 2 dimension residual is chosen for use in further steps. Various other preprocessing and post-processing steps are employed for GBA data validation and QC. In particular, controls producing a known reaction value may be employed to assure integrity of the biochemical process. In a preferred embodiment, signals are assumed to be small positive numbers (between 0.0 and 5.0, with 0.0 indicating that allele is likely not present in the sample, and larger values indicating that it may be.

To handle a wide range of input data signal strengths, the Adaptive Fitting Variation is employed. However, the program is hard-coded to perform exactly one or two interactions passes through step 25, which we find works well for existing GBA data.

The probability distributions we fit at present in steps 22 and 25 have as their only parameters (i) the ratio of the X and Y signals for heterozygotes, and (ii) the variance from the normalized means (0.0 negative for that allele, 1.0 for positive for that allele) along each axis separately. In fact, these later numbers are constrained to be at least a fixed minimum, which is rarely exceeded, so that the algorithm will work with very small quantities of data and will produce the behavior we want. These numbers are computed separately for each microtiter plate. The probability distributions are generated using the code

(written in C) attached hereto and incorporated herein by reference as Appendix A.

The Null-Class variant is used to provide genotypic class indicating No Signal.

Quality control may also be enhanced in a surprising manner using the procedures described here. In particular, the confidence score C of equation (4) serves as a robust indicator of the performance of the biochemical reaction system. For example, a downward trend in the confidence scores within a single batch or in successive batches may indicate deterioration of an important reagent or of a sample or miscalibration of the instrumentation.

Accordingly, in a preferred embodiment, the computer may be used to determine the presence of a downward trend in the confidence score over time calculated in reference to each of the following variables: the locus (is there a downward trend in the confidence score of a single locus relative to other loci tested?), the sample (is there a downward trend in the confidence score of a single sample relative to other samples tested?), plate (is there a downward trend in the confidence score of this plate relative to other plate?), and batch (relative to other batches). If a downward trend of statistical significance (using, for example a chi square test) is detected, an alarm condition is entered.

Because the confidence score is an accurate indication of the reliability of the reaction system and the genotype determination, a low confidence score associated with a

given determination is taken as indicating the need for retesting.

APPENDIX A

}
```

What is claimed is:

1. A method of determining the genotype at a locus within genetic material obtained from a biological sample, the method comprising:

A. reacting the material at the locus to produce a first reaction value indicative of the presence of a given allele at the locus;

B. forming a data set including the first reaction value;

C. establishing a distribution set of probability distributions, including at least one distribution, associating hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus;

D. applying the first reaction value to each pertinent probability distribution to determine a measure of the conditional probability of each genotype of interest at the locus; and

E. determining the genotype based on the data obtained from step (D).

2. A method according to claim 1, wherein the distribution set includes a plurality of probability distributions for a corresponding plurality of genotypes of interest.

3. A method, according to claim 1, further comprising:

(i) reacting the material at the locus to produce a second reaction value independently indicative of the presence of a second allele at the locus;

(ii) forming a second data set including the second reaction value; and

(iii) applying the first and second reaction values to each pertinent distribution to determine a measure of the conditional probability of each genotype at the locus.

4. A method according to claim 2, further comprising:

(i) reacting the material at the locus to produce a second reaction value;

(ii) applying the first and second reaction values to each pertinent distribution to determine the probability of each genotype at the locus; and

(iii) applying the first and second reaction values to each pertinent distribution to determine a measure of the conditional probability of each genotype at the locus.

5. A method according to claim 3, wherein each probability distribution associates a hypothetical pair of first and second reaction values with a single probability of each genotype of interest.

6. A method according to claim 4, wherein each probability distribution associates a hypothetical pair of

first and second reaction values with a single probability of each genotype of interest.

7. A method according to claim 1, wherein:

step (B) includes the step of including in the data set other reaction values obtained under conditions comparable to those under which the first reaction value was produced; and

step (C) includes the step of using the reaction values in the data set to establish the probability distributions; the method further comprising:

performing steps (D) and (E) with respect to each of the reaction values.

8. A method according to claim 2, wherein:

step (B) includes the step of including in the data set other reaction values obtained under conditions comparable to those under which the first reaction value was produced; and

step (C) includes the step of using the reaction values in the data set to establish the probability distributions; the method further comprising:

performing steps (D) and (E) with respect to each of the reaction values.

9. A method according to claim 3, wherein:

step (B) includes the step of including in the data set other reaction values obtained under conditions

comparable to those under which the first reaction value was produced; and

step (C) includes the step of using the reaction values in the data set to establish the probability distributions; the method further comprising:

performing steps (D) and (E) with respect to each of the reaction values in the first and second data sets.

10. A method according to claim 4, wherein:

step (B) includes the step of including in the data set other reaction values obtained under conditions comparable to those under which the first reaction value was produced; and

step (C) includes the step of using the reaction values in the data set to establish the probability distributions; the method further comprising:

performing steps (D) and (E) with respect to each of the reaction values in the first and second data sets.

11. A method, according to claim 7, of determining the genotype at a locus within genetic material obtained from each of a plurality of samples, the method further comprising:

(1) performing step (A) with respect to the locus of material obtained from each sample;

(2) in step (B), including in the data set reaction values obtained from each sample.

12. A method according to claim 7, of determining the genotype of selected loci within genetic material obtained from a sample, the method further comprising:

(1) performing step (A) at each of the selected loci;

(2) in step (B), including in the data set reaction values obtained from each of the selected loci.

13. A method according to claim 7, wherein step (C) includes:

(1) establishing a set of initial probability distributions that associate hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus;

(2) using the initial probability distributions to determine measures of the initial conditional probability for each genotype at the locus; and

(3) using the results of step (2) to modify the initial probability distributions, so that the modified distributions more accurately reflect the reaction values in the data set.

14. A method according to claim 8, wherein step (C) includes:

(1) establishing a set of initial probability distributions that associate hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus;

(2) using the initial probability distributions to determine measures of the initial conditional probability for each genotype at the locus; and

(3) using the results of step (2) to modify the initial probability distributions, so that the modified distributions more accurately reflect the reaction values in the data set.

15. A method according to claim 9, wherein step (C) includes:

(1) establishing a set of initial probability distributions that associate hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus;

(2) using the initial probability distributions to determine measures of the initial conditional probability for each genotype at the locus; and

(3) using the results of step (2) to modify the initial probability distributions, so that the modified distributions more accurately reflect the reaction values in the data set.

16. A method according to claim 10, wherein step (C) includes:

(1) establishing a set of initial probability distributions that associate hypothetical reaction values with corresponding probabilities for each genotype of interest at the locus;

(2) using the initial probability distributions to determine initial conditional probabilities for each genotype at the locus; and

(3) using the results of step (2) to modify the initial probability distributions, so that the modified distributions more accurately reflect the reaction values in the data.

17. A method according to claim 13, wherein step (C) further includes:

(4) repeating steps (1) through (3) a desired number of times.

18. A method according to claim 14, wherein step (C) further includes:

(4) repeating steps (1) through (3) a desired number of times.

19. A method according to claim 15, wherein step (C) further includes:

(4) repeating steps (1) through (3) a desired number of times.

20. A method according to claim 16, wherein step (C) further includes:

(4) repeating steps (1) through (3) a desired number of times.

21. A method according to claim 1, wherein step (E) further includes the step of calculating a confidence score, associated with the genotype being determined, based on data obtained from step (D).

22. A method according to claim 3, wherein step (E) further includes the step of calculating a confidence score, associated with the genotype being determined, based on data obtained from step (D).

23. A method according to claim 7, wherein step (E) further includes the step of calculating a confidence score, associated with the genotype being determined, based on data from step (D), the method further comprising (F) determining whether a significant downward trend in confidence scores has occurred, and, in such event, entering an alarm condition.

24. A method according to claim 9, wherein step (E) further includes the step of calculating a confidence score, associated with the genotype being determined, based on data from step (D), the method further comprising (F) of determining whether a significant downward trend in confidence scores has occurred, and, in such event, entering an alarm condition.

25. A method according to claim 1, wherein each allele is a single specific nucleotide.

26. A method according to claim 4, wherein each allele is a single nucleotide.

27. A method according to claim 1, wherein each allele consists of at least two specific nucleotides.

28. A method according to claim 4, wherein each allele consists of at least two specific nucleotides.

29. A method according to claim 1, wherein each allele is defined at least in part by its length in nucleotides.

30. A method according to claim 4, wherein each allele is defined at least in part by its length in nucleotides.

31. A method according to claim 1, wherein each allele is defined by one of the presence and absence of at least one restriction site.

32. A method according to claim 4, wherein each allele is defined by one of the presence and absence of at least one restriction site.

33. A method according to claim 4, wherein step (B) includes the step of including in the data set reaction values from prior tests at the locus obtained under

comparable conditions.

34. A method according to claim 12, wherein the loci are selected on the basis of their ability to discriminate among subjects.

35. A method, according to claim 3, wherein the step A of reacting the material involves using a different reaction from that of step A and the second allele is different from the given allele.

36. A method according to claim 1, wherein step (A) includes the step of assaying for the given allele using genetic bit analysis.

37. A method according to claim 1, wherein step (A) includes the step of assaying for the given allele using hybridization.

38. A method, according to claim 1, wherein step (A) includes the step of assaying for the given allele using allele-specific amplification.

39. A method, according to claim 1, wherein step (A) includes the step of assaying for the given allele using a polymerase chain reaction.

40. A method, according to claim 1, wherein step

(A) includes the step of assaying for the given allele using a ligase chain reaction.

41. A method according to claim 12, wherein the loci are proximal to one another, so that the set of genotypes so produced may indicate a sequence of nucleotides associated with the genetic material.

42. A method of determining the genotype of a subject, the method comprising:

A. reacting genetic material taken from the subject at selected loci, each locus being an identified single nucleotide, to produce with respect to each of the selected loci a reaction value indicative of the presence of a given allele at each of the selected loci;

B. using the reaction values to determine the genotype of the subject and a confidence score, associated with the genotype being determined.

43. A method according to claim 42, wherein the loci are selected to provide information pertaining to inheritance of a trait.

44. A method according to claim 42, wherein the loci are selected to provide information pertaining to parentage of the subject.

45. A method according to claim 42, wherein the

loci are selected to provide information pertaining to the identity of the subject.

46. A method according to claim 42, wherein the loci are selected to provide information pertaining to matching tissue of the subject with that of a donor.

47. A method according to claim 42, wherein the loci are spaced throughout the entire genome of the subject to assist in characterizing the genome of the species of the subject.

TRANSMITTAL OF DECLARATION

Sir:

Attached is a copy of the declaration from the grandparent application serial No. 08/362,266. Please note that the power of attorney for Howrey & Simon has been revoked and Kalow Springut & Bressler LLP are now the attorneys of record.

If the Examiner has any questions regarding this matter, or more information is needed, it is respectfully requested that the Examiner contact Applicants' undersigned attorney at the telephone number provided below.

Respectfully submitted,

Franklin Abrams

DECLARATION AND POWER OF ATTORNEY

We, the below named inventors, hereby declare that:

Our residences, post office addresses, and citizenships are as stated below next to our respective names.

We believe we are the original, first, and joint inventors of the subject matter which is claimed and for which a patent is sought on the invention entitled **AUTOMATIC GENOTYPE DETERMINATION**, the specification of which:

was filed December 22, 1994 as serial no. 08/362,266.

We hereby state that we have reviewed and understand the contents of the above identified specification, including the claims.

We acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56(a).

We hereby appoint the following attorneys:

	Registration No.
Bruce D. Sunstein	27,234
Robert M. Asher	30,445
Timothy M. Murphy	33,198
Harriet M. Strimpel	37,008

all of the firm BROMBERG & SUNSTEIN, to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

We request that all correspondence be directed to:

BROMBERG & SUNSTEIN
125 Summer Street
11th Floor
Boston, MA 02110

Attn: Bruce D. Sunstein

and all telephone calls should be directed to:

Bruce D. Sunstein (617) 443-9292

We hereby declare that all statements made herein of our own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements are made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

Stephen E. Lincoln
Full name of **first** inventor

Stephen	E.	Lincoln
First name	Middle initial	Last name

Inventor's signature: 

Date: 4/5/95 Country of Citizenship: US

Residence: 325 Limestone Valley Drive, Cockeysville, Maryland 21030

Post Office Address: same as residence

Michael R. Knapp
Full name of **second** inventor

Michael	R.	Knapp
First name	Middle initial	Last name

Inventor's signature: 
Date: 3-30-95 Country of Citizenship: US

Residence: 2630 N. Calvert Street, Baltimore, Maryland 21218

Post Office Address: same as residence

ADDED PAGE TO DECLARATION AND POWER OF ATTORNEY
FOR DIVISIONAL, CONTINUATION, OR CIP APPLICATION

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) that is/are listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in that/those prior application(s) in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose information that is material to the examination of this application, namely, information where there is substantial likelihood that a reasonable examiner should consider it important in deciding whether to allow the application to issue as a patent, which occurred between the filing date of the prior application(s).

Prior U.S. application

Serial No.	U.S. Filing Date	Patented	Pending	Abandoned
